Summary of Cisco Secure Remote Administration & AAA

So we started by working with our windows 11 computer in class and the Cisco switch. We physically connected the computer to the switch using the console cable to connect to the console port on the switch so we could access and configure it. We also used the blue ethernet cable to connect the computer and the switch so they could communicate over the network.
We then configured the switch's VLAN 1 management interface with an IP address and verified that interface was active and had the correct IP address.
After configuring the management IP, we made sure the Windows 11 computer and the Cisco switch could communicate on the same network. We then configured SSH on the switch so that we could manage it remotely. We created a local administration account and tested the SSH connection to make sure we could successfully login into the switch.
After that we started setting up the AAA server, (authentication, authorization, and accounting). The computer was used as the AAA server, running TEKRADIUS and TACAS.net , and the cisco switch act as the aaa client. I learned that the switch can send a user's login request to the AAA server to verify their credential and access, which provides centralized control on who can manage the switch. Overall, the main reason why we did the switch was to securely manage the Cisco switch remotely and use a centralized AAA server to control and authenticate users who access the switch.
